Antisense oligonucleotides (ASOs) have been used successfully in the treatment of Duchenne muscular dystrophy, but the large

molecular mass of the dystrophin protein precludes intracellular delivery. To investigate the feasibility of using ASOs to develop a therapy for this disease, we designed a morpholino that targets the region within the dystrophin pre-mRNA that codes for the C-terminal domain of the protein. We injected this morpholino into zebrafish embryos at 14 h post-fertilization and examined its effect on the neuromuscular junction in fixed retinal explant preparations. Using neuronal labeling, we identified the postsynaptic side of the neuromuscular junction. After treatment with an antisense morpholino, we noted a reduction in the number of synaptic vesicles at the presynaptic side of

the synapse compared to the control embryos. These results indicate that the antisense morpholino may be used to develop a therapy for Duchenne muscular dystrophy.
