A: This look like a single sign-on (SSO) ticket. You can do two things: Use Authentication Tag, since this ticket is related to a user. In this way, you can disable the second column. Use the IP related ticket. In this way, you can also disable the second column, so the user don't know what is his real IP. However, he will only know the IP of the system he logged from. Q: C++ running virtual machine I am currently a newbie and need help with a practice problem for a class. We have to have a computer that uses a virtual machine to run a simple operating system. We are limited to utilizing OpenSSH for encryption, built in BSD commands and a built in shell (so no boost of any kind). For the virtual machine we have to have a memory of 3MB, my full program would probably need about 200MB or so. I am just trying to figure out the best way to get started. I know how to build a shell. I read through the link provided and it seems like there is some sort of interface program that I am not sure how to use. A: The best way to go about that is to use the OpenBSD core. You will want to look up "pkg" and "sg3sd" for creating a guest os. There are a few other tools as well, but those are the big 3 that I would look up. A: Your best bet would be to look at QEMU, the Xen virtual machine implementation. It's commonly used to emulate x86 architectures and run operating systems within them. A: There are quite a few VMs out there, mostly written in Java, and generally used for systems programming, or Web development. This may be a good starting point: Good f30f4ceada
