Harvesting pre-teenage genes from tooth germs could help to predict a person's future height, research suggests. An international team of scientists has analyzed genes from stem cells obtained from tooth germs of children as they grow. "Using the methods developed, we can have real time information from what may be an early stage in tooth development," Why It Matters The technique could provide a way to predict future adult height, the authors suggest. Pre-teenage growth is known to be the most accurate indicator of adult height, and the genetics of pre-teen growth have been studied for a long time. "It's the most representative signal from an individual that we can get," Why It Matters The team has now used their technique on teeth to determine which genes are expressed before their developing into adult teeth. This has allowed them to see which genes are affected during very early tooth development, which genes affect the function of nerves and bones, and which genes affect the number of teeth each individual will have. "This research is the first time that these particular genes have been shown to be active in this location during the early tooth development process," Dr Phillipa Attard-Montalto, of the University of Exeter's Centre for Craniofacial Anomalies and Microdevelopmental Disorders
