The following descriptions describe the theoretical basis for smoothing the output signal in the Decimator module. A certain amount of smoothing is often applied to the signal in a digital input module to minimize the effect of noise. This smoothing, however, can reduce the resolution of the input signal, or alias the input signal to other frequencies, if done too much. [Diagnosis of obstructive sleep apnea syndrome in children]. Obstructive sleep apnoea syndrome (OSAS) is characterized by recurrent episodes of upper airway obstruction, which usually occur during sleep. It is a very common disorder in children, probably as much as in adults. Children can develop "simple" OSAS, in which the apnoea and hypopnoea events are triggered by upper airway obstruction. More frequently, the obstructive events are generated by collapse of the oropharyngeal structures. The consequences of OSAS in children are serious, including sleep fragmentation, daytime somnolence, poor neurocognitive development, reduced growth and obesity, with significant associated morbidity and mortality. The diagnosis of OSAS in children is a challenge because of their intermittent nature of symptoms, their variability, and the fact that they can mimic common conditions (notably, viral illness, gastroesophageal reflux and asthma). Diagnostic techniques include: polysomnography, which requires a full night of recording; nocturnal oximetry, which provides an index of the severity of the disease; and questionnaires, which assess how often the child has symptoms, and the impact that they have on family and school life. It is necessary to evaluate the degree of sleep disturbance, the risk of these events occurring, and the presence of alternative diagnostic hypotheses. In children, the most appropriate tests are: a thorough physical examination; a clinical interview; an examination of possible comorbidities; the same type of sleep questionnaires used in adults; and polysomnography. The objective of the treatment is to correct the underlying disorder, avoid further complications, and improve the quality of life of the child and family. An alias mask for use with the ENVELOP. The first octet indicates the data type of the key, which may be either BLOCK or SEQ. The second and third octets indicate the length of the key in bits, and the next octet indicates whether the key is hexadecimal or binary. The remaining octets indicate the length of the output in bytes, and the last octet indicates the length of the output in bits. The length of the output is not a multiple of four, but the output is padded on the right with 0x00 if it is less than a multiple of four, and the padding is truncated if it is more than a multiple of four. KEYHEX Description: A key in hexadecimal. This is a fairly standard format for keyboards and hardware implementations. The first byte indicates the size of the key in bits, and the other bytes are the key code, starting at bit 7. KEYBLOCK Description: A key in binary. This is the standard format for keyboards and hardware implementations. The first byte indicates the size of the key in bits, and the other bytes are the key code, starting at bit 7. KECHAL Description: The characters for keying. The default is to use the default KECHAL of "k". AUTHCTRL1 Description: Control the authentication. If the chip is in normal mode, it will be in normal mode if this control byte is set to 0xA. If the chip is in test mode, it will be in test mode if this control byte is set to 0xB. This control byte controls the authentication of the key, which is used to disable the use of the entered key as the key in the last cycle. It is the only byte that must be set to 0xA or 0xB, and it is also the only one that must be set. The next byte in the sequence must be set to 0xA, 0x0A, 0x0B, or 0x0B to specify a state transition. AUTHCTRL2 Description: Controls how the keys are used for the next operation. When in normal mode, a simple key is sent as a key sequence. When in test mode, the next key is always
