Prolonged partial molar pregnancy and gestational trophoblastic disease are life-threatening conditions that can be successfully treated by conservative therapeutic interventions. To determine whether the use of a fresh blastocyst transfer may be justified in the treatment of these patients, we evaluated our experience with 16 patients with a complete hydatidiform mole or partial hydatidiform mole who had undergone a fresh blastocyst transfer at our centre from January 1, 1990, to August 15, 1999, with a subsequent complete spontaneous molar regression. In all 16 patients, the development of complete spontaneous regression was documented after the fresh blastocyst transfer. In all, complete remission was achieved in 15 patients (94.2%) and partial remission in 1 patient (6.3%) after a mean time to remission of 14 days (range, 5-33 days). In the patient with partial remission, an ectopic site was found in the initial pelvic ultrasound and a gestational trophoblastic disease was suspected. After 1 cycle of chemotherapy and a repeat ultrasound, complete remission was achieved. No patient in this group was lost to follow-up. The mean pregnancy duration time for all patients was 24.7 weeks (range, 8-32 weeks). The use of a fresh blastocyst transfer has the theoretical advantages of reducing the risk of uterine rupture and producing a live birth at term. The safety and effectiveness of the procedure are supported by the results of this study, showing a pregnancy loss rate of 6.3%, and no treatment-related complications.Remarkable trends of the conjugated C[triple bond]C functional group in synthetic polymers and applications: Part II. This communication reviews remarkable trends of the conjugated C[triple bond]C group in synthetic polymers and applications (Part II).
