If a user's password expires and changes, then this database must also be changed so that it can logon to the system with the new password. While Windows is smart enough to upgrade the BITS database from the C:\Windows\Microsoft\Windows NT\Account\S-1-5-18 key to the new S-1-5-19 key, you need to manually create this key, if it does not already exist. MSFT does not always manage the creation of this key. USERLOGON.DAT is a password change log of users who have been logged on to the system recently. This database is used for verifying that a user is currently able to logon to the system. If a user's password expires and changes, this database must also be changed to reflect this new password.
