cancer is the leading cause of
cancer deaths in both men and
women in the United States and is
a major worldwide problem. It is
estimated that there will be about
1.3 million new cases of lung
cancer in 2001 and the death rate
is about 1 in 2 (Boring et al. CA:

A Cancer Journal for Clinicians
51:23-45, 2001). Despite
advances in detection and
management of lung cancer, the 5
year survival rate is only 15% and
many patients die from
recurrence within one year.
Current treatment strategies for
early-stage lung cancer include
surgery for small tumors that can
be completely resected, and
medical therapy for early-stage
non-small cell lung cancers
(NSCLC). Standard first-line

treatment of advanced NSCLC includes platinum-based chemotherapy (e.g., cisplatin or carboplatin). Combination chemotherapy with paclitaxel and carboplatin is one of the standards of care for NSCLC patients, which is now an accepted regimen for the treatment of patients with advanced disease. However, most patients develop drug resistance, and ultimately have an unfavorable outcome

(Stathopoulou et al. Lancet 359:832-836, 2002). One of the major barriers to the development of lung cancer therapy is the failure to detect small subpopulations of cells that exhibit the ability to self-renew and to differentiate into multiple distinct cellular lineages. The identification and characterization of the biological and clinical significance of stem cells has emerged as one of the most important recent advances

in cancer research. These cells are believed to play an important role in the growth, recurrence, and metastasis of tumors. They have been implicated in tumorigenesis, cancer metastasis, tumor drug resistance, cancer recurrence, and therapeutic resistance. Various cellular
