Lately, researchers have found that keyloggers are no longer the exception but are now the norm for keyloggers. Keyloggers allow an attacker to take over the target computer from a remote location and intercept every keystroke that occurs on the computer. Because of this, companies have introduced security measures such as keyloggers in order to monitor their employees' computer usage and for the sake of workplace security and employee productivity. Today's computers are very capable and contain many vulnerabilities. The goal of a keylogger is to place software on a user's machine and remotely collect everything the user types. Keystroke logging is not the only security breach that can occur on a computer. Many other types of potential security breaches can happen on a computer, such as:

- Keylogging, password capture and compromise
- Footprinting
- Hijacking
- Monitor/keystroke-logger
- Trojan horse
- Worms/viruses

Keystroke logging malware often attaches itself to other malware. So it would be prudent to use a keylogger to detect malicious software and malware. A keylogger can detect malware without being installed or present on the computer. Another reason why keyloggers are so useful is that they work in all operating systems and hardware configurations. Companies like to protect their computers in the event that someone gets a hold of their computer. They can do this by disabling keyboard hotkeys and preventing the user from performing certain functions or they can prevent a user from being able to log-in to their computer remotely. A good way to do this is to log keystrokes for the duration of the computer being infected. It is also important to mention that even if a user is turned on and logged in to the computer, keyloggers can still capture keystrokes. A keylogger can log a number of things, the most common is the input of the user's login credentials (e.g., password, pass phrase, etc.). The login information is then transferred to an attacker who can then steal the login credentials and use them to infiltrate a computer network. Other logins that can be logged include sensitive data like credit card numbers and login information for online banking. This data can be transferred to an attacker. If a user logs on to a computer without using the keystrokes, an attacker can still capture the keystrokes by using another way. They can also capture the screen from the victim's computer, so they can see what the victim is typing. A key 77a5ca646e
