
A simple, straightforward process starts off by writing down the length of the hypotenuse. Afterwards, you need to specify the angle it forms with the adjacent. This bit of info is enough for the application to automatically calculate rest of details, such as slope percentage, adjacent, and opposite lengths, as well as the second angle, considering one of them is 90 by default. You can either take another shot at it, or quit. Sadly, history is not kept track of, even if you continue with a new triangle. What's more, you need to take the time to manually write down values where needed, because there's no possibility to save results to file. Since it's a command line utility, don't expect to actually see the triangle.

Q: Client-Server with Node.js I have an idea to work on a kind of Client-Server architecture, where I'd have a Node.js server and 3 Android devices connecting to it and sending some commands to the server. I also have an idea to go the whole way and use a Web Socket but I'd like to know if a Node.js server and 3 Android devices connected to it will work, if there are any problems regarding security and etc.

A: You can use Socket.io and the Socket.IO-Android-Client for that.
