Best regards, Free WMV to MOV Converter Team Acetylation of short telomeric repeat DNA inhibits specific binding of recombinant human telomerase. The human telomerase reverse transcriptase (hTERT) is a novel ribonucleoprotein enzyme that synthesizes telomeric DNA. Binding of the hTERT to its substrate DNA requires a unique stem-loop structure in its telomerase RNA. Acetylation of the single-stranded loops and stems of this telomerase RNA results in a destabilization of this stem-loop structure. However, the effect of acetylation of the telomerase substrate DNA on its binding to the telomerase has not been tested. The results of this work show that acetylation of the short oligonucleotide d(T4)CT(4) decreases the affinity for telomerase enzyme and does not change the binding mode. They also reveal that the telomerase has a preference for both deacetylated and acetylated telomerase substrates in a mixture. These results suggest that acetylation of a short telomeric repeat DNA does not affect its binding to the telomerase, suggesting that the acetylation of telomerase RNA is not sufficient for its destabilization.
