With it you can combine several data sources, create workflows, process data and share your results in the cloud. Expression of DNA repair genes in human oral squamous cell carcinomas and oral fibromas: evidence of oxidative stress involvement. DNA damage by reactive oxygen species (ROS) is involved in the development of oral squamous cell carcinomas (OSCC) and oral fibromas (OF), suggesting that the antioxidant defenses may play a role in this process. We evaluated expression of genes encoding for antioxidant enzymes (catalase, superoxide dismutase, glutathione peroxidase and thioredoxin reductase), the major scavenger of ROS, by reverse transcription-polymerase chain reaction (RT-PCR). The results showed that expression of these genes was different in the two types of lesions. Expression of catalase and thioredoxin reductase was higher in OF than in OSCC. In OSCC, catalase and thioredoxin reductase expression was associated with TNM stage and tumor size, suggesting that the expression of antioxidant genes could be part of an early response to oxidative stress in OSCC.
